

Case by Dr. Michael Sonick

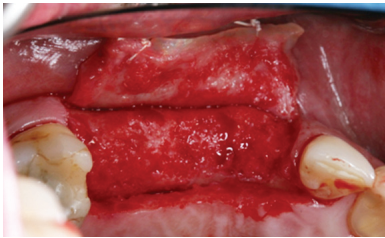

Maxillary left premolar and canine teeth periodontally compromised and grossly decayed

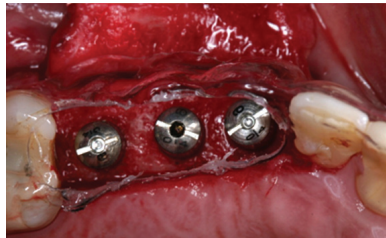

Pre-op radiograph confirms clinical diagnosis

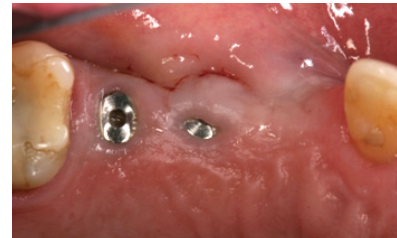

Augmented left maxillary alveolar ridge five months after grafting procedure

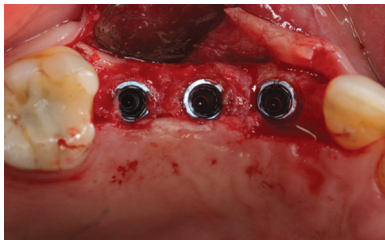

Excellent ridge form for implant placement at five months post-grafting

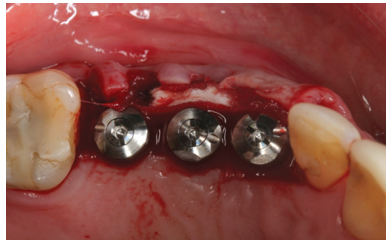

Implants placed and healing abutments inserted five months post ridge augmentation surgery

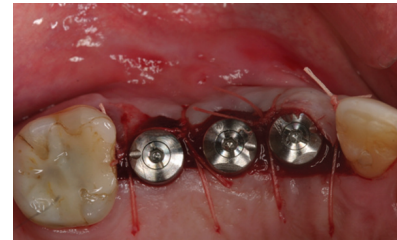

Seven months post implant placement with inadequate buccal soft tissue contour and thickness

Second stage surgery seven months following implant placement

At second stage surgery, Mucograft® is placed between the buccal cortex and the mucoperiosteal flap to improve soft tissue thickness and contour

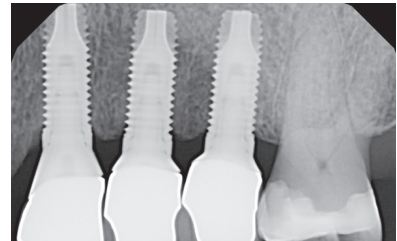

Following placement of Mucograft®, flap closed via interrupted sutures

After sutures removed improved soft tissue contour and thickness are noted

Seven months following implant placement, definitive implant-supported restoration in place

Radiograph seven months following implant placement reveals excellent osseointegration
